

Statistical bulletin

Model-based early estimates of regional gross value added in England, Wales, Scotland, and Northern Ireland: Quarter 1 (Jan to Mar) 2022

Experimental model-based estimates of quarterly regional gross value output for the nine English regions, Wales, Scotland and Northern Ireland.

1 . Other pages in this release

- [Model-based estimates of regional GVA: an overview](#)

2 . Main points

- These experimental estimates are produced using an econometric model, an overview of which is provided in the [Model-based estimates of regional GVA accompanying article](#).
- The [Model-based estimates of regional GVA accompanying article](#) provides a historic comparison with the Office for National Statistics' (ONS') previously published [GDP, UK regions and countries](#) quarterly estimates, which these estimates are an early indication of.
- All nine English regions, Wales, Scotland, and Northern Ireland are estimated to have seen a positive quarter-on-previous-quarter growth in gross value added (GVA) in Quarter 1 (Jan to Mar) 2022, ranging from 0.4% to 1.2%.
- The modelled estimates are based on historical relationships, so regional shocks for the reported quarter will not be detected, and the results should therefore be treated with some caution; development work is being conducted with a view to add more timely regional indicators into the model to aid detection of regional shocks.
- Following user feedback, the model has been updated to allow the inclusion and constraint to Quarter 4 (Oct to Dec) 2021 of the [Scottish Government's gross domestic product \(GDP\)](#) and [Northern Ireland Statistics and Research Agency's \(NISRA's\) NI Composite Economic Index \(NICEI\)](#). More information is given in the [Measuring the Data section](#).
- The most up-to-date data inputs available at the time of compilation are used, which includes the [GDP, UK regions and countries](#) bulletin published on 31 May 2022 and the latest [annual regional economic activity, by gross domestic product](#) bulletin published on 30 May 2022, but does not include [Scotland's first estimate of GDP for Quarter 1 \(Jan to Mar\) 2022](#), published on 1 June 2022.

3 . Model-based estimates of regional gross value added (GVA)

These estimates of seasonally adjusted growth are modelled from a variety of data sources, including the [first estimate of UK gross domestic product \(GDP\)](#) for Quarter 1 (Jan to Mar) 2022, the [GDP, UK regions and countries](#) bulletin published on 31 May 2022 and the latest [annual regional economic activity, by gross domestic product](#) bulletin published on 30 May 2022.

The regional estimates are subject to a degree of uncertainty expressed as confidence intervals. More information is available in the [Measuring the data section](#).

Users should be cautious when comparing these estimates with other existing regional estimates or the national estimates because the methodologies used to compile them differ. Information on how to interpret these data, and their strengths and limitations, can be found in the [Measuring the data](#) and [Strengths and limitations](#) sections.

Figure 1: All regions and countries are estimated to have seen a positive quarter-on-previous-quarter growth in gross value added (GVA) in Quarter 1 (Jan to Mar) 2022

Model-based estimates of regional GVA growth for the English regions, Wales, Scotland, and Northern Ireland for Quarter 1 2022

Download this chart

[.xlsx](#)

The [first quarterly estimate of GDP](#) at UK level for Quarter 1 2022 estimated [gross value added \(GVA\)](#) in basic prices to have increased by 0.8% quarter-on-quarter.

The model-based estimates of regional GVA indicate that the East Midlands, London, and Wales had greater growth than the UK-wide figure in Quarter 1 2022 (Figure 1). The highest was London with 1.2% growth.

The model estimates that the East of England, South East, West Midlands, North West, Scotland and Northern Ireland had growth below the UK GVA. The lowest was Northern Ireland with 0.4% growth. The North East, Yorkshire and The Humber, and the South West have estimated growth equal to the UK GVA of 0.8% growth.

This bulletin presents data as quarter-on-quarter growth percentage rates and indices of the model-based estimates in this publication. Once the methods used to produce our [GDP, UK regions and countries](#) bulletin (which is an input to these model-based estimates) have been refined, revisions to historical estimates will be incorporated.

4 . Methodology of the model

The model used to produce the estimates utilises a mixed-frequency vector autoregressive (MF-VAR). This is described in technical detail in [UK Regional Nowcasting using a Mixed Frequency Vector Autoregressive Model](#).

The Economic Statistics Centre of Excellence (ESCoE) nowcast model initially takes the latest figure for UK gross domestic product (GDP) growth. It then forms an estimate for each region of England, Wales, Scotland and Northern Ireland, based on the four factors noted in the following paragraph. This ensures the weighted sum of regional changes is consistent with the change in aggregate UK GDP.

There are four main methodological processes in the model, which are used to create the estimates. These are:

- estimated historical relationships between regional growth and UK growth (this reflects how sensitive regional growth is to UK growth)
- estimated historical relationships between the growth of particular regions (this captures how growth in one region has translated into growth in another region)
- estimated historical relationships within the regions (this captures the persistence of regional growth from one quarter to the next)
- estimated historical relationships between other macroeconomic variables and regional growth (for example, how oil price changes can have a large impact on all regions, particularly with the additional UK quarterly macroeconomic variables, so there can be substantial increases in the connection between measures for the oil price and the exchange rate)

Further information is available on the [ESCoE website](#).

5 . Model-based estimates of regional gross value added (GVA) data

[Model-based early estimates of regional gross value added \(GVA\) in the regions of England, Wales, Scotland, and Northern Ireland](#)

Dataset | Released 7 June 2022

Experimental model-based estimates of quarterly regional gross value added (GVA) output for the nine English regions (North East, North West, Yorkshire and The Humber, East Midlands, West Midlands, East of England, London, South East, and South West), Wales, Scotland, and Northern Ireland.

[Model-based regional gross value added \(GVA\) revisions triangle](#)

Dataset | Released 7 June 2022

Model-based regional GVA estimates based on running the model that transitioned from the Economic Statistics Centre of Excellence (ESCoE) to the Office for National Statistics (ONS) in “real time” from Quarter 2 (Apr to June) 2019.

6 . Glossary

Mixed-frequency vector autoregressive (MF-VAR)

A MF-VAR approach estimates the set of regressions (for example, one for each variable in the model) as a system. This allows us to take advantage of the interactions between variables to improve the fit of the model. In this case, we expect there to be correlations between the gross domestic product (GDP) growth across regions, so a MF-VAR framework enables this information to be used rather than if we had a separate forecast model for each region. The explanatory variables in each regression are past values of all the other variables in the model.

Gross value added (GVA)

GVA is the value of an industry's outputs minus the value of intermediate inputs used in the production process.

Output approach to gross domestic product (GDP)

When using the output approach to measuring GDP, we are actually estimating the contribution of each industry or producer by using GVA at basic prices. Put simply, the value of a unit's outputs minus the value of inputs used in the production process to produce the outputs. The basic price is the amount that the producer receives for a unit of a good or service that is produced. As such, it includes any subsidies that are received on products but excludes any taxes that are payable on those products.

GVA at basic prices plus taxes on products minus subsidies on products equals GDP at market prices (or headline GDP).

7 . Measuring the data

These model-based estimates are designated as [experimental statistics](#) while in development and are subject to revision. They should therefore be interpreted with some caution. Recent regional shocks will not be detected because the model relies on estimated historical relationships.

We will continue to develop the model and invite users' views on their uses and needs for these data. We welcome feedback to help inform our development work at regionalgdp@ons.gov.uk.

Model-based estimates of regional gross value added (GVA)

This release contains modelled estimates of regional GVA, published approximately three weeks after the Office for National Statistics' (ONS') release of the first estimate of gross domestic product (GDP).

The model provides regional estimates for a given quarter around five months ahead of our [GDP, UK regions and countries bulletin](#). This bulletin series covers the nine English regions and Wales and is based mainly on HM Revenue and Customs (HMRC) Value Added Tax (VAT) data.

In past publications, the model was not constrained to the latest published estimates for Scotland and Northern Ireland. Following user feedback, this limitation has now been addressed. In this release, the model is constrained to the Quarter 4 (Oct to Dec) 2021 estimates for Scotland and Northern Ireland. This has caused some revisions because of changes in the model parameter estimates as the relationships between the regions are recalculated given the incorporation of new data points. The current estimates are not constrained to [Scotland's first estimate of GDP for Quarter 1 \(Jan to Mar\) 2022](#), published on 1 June 2022, as this was not available when the model inputs were compiled. Therefore, for this latest quarter, we would recommend that users view the official estimates for Scotland.

Future publication date of regional estimates

[Scottish Government's first estimate of GDP](#)

The Quarter 2 (Apr to June) 2022 estimates are expected to be published 31 August 2022.

[Northern Ireland Statistics and Research Agency's \(NISRA's\) NI Composite Economic Index \(NICEI\)](#)

The Quarter 1 (Jan to Mar) 2022 estimates are expected to be published 7 July 2022.

[Welsh Government's short-term output indicators](#)

The Quarter 1 (Jan to Mar) 2022 estimates are expected to be published 28 July 2022.

[ONS' GDP: UK regions and countries bulletin \(covering the nine English regions and Wales\)](#)

The Quarter 1 (Jan to Mar) 2022 estimates are expected to be published November 2022.

The Quarter 4 (Oct to Dec) 2021 estimates are expected to be published August 2022.

Quality

More quality and methodology information on strengths, limitations, appropriate uses, and how the data were created is available in the accompanying article, [Model-based estimates of regional GVA](#).

As an indication of quality for the quarterly modelled estimates, Table 1 provides approximate confidence intervals calculated from the root mean square errors (RMSE) of the model, compared with ONS' [GDP, UK regions and countries: July to September 2021 bulletin](#) published on 31 May 2022, as well as the [Scottish Government](#)'s and [NISRA](#)'s Quarter 4 (Oct to Dec) 2021 publications.

As an example of how to interpret the confidence intervals in Table 1, the model estimated the South West to have increased by 0.8% in Quarter 1 (Jan to Mar) 2022. The confidence interval indicates 95% confidence that the true growth will lie between negative 0.9% and positive 2.5%.

Table 1: Confidence Interval Root Mean Square Error (RMSE), relative to the published estimate

Region	Q2 2019 to Q3 2021 excluding Q2 and Q3 2020
East Midlands	estimate plus or minus 2.7%
East of England	estimate plus or minus 2.3%
London	estimate plus or minus 2.3%
North East	estimate plus or minus 2.9%
North West	estimate plus or minus 1.3%
Northern Ireland	estimate plus or minus 1.6%
Scotland	estimate plus or minus 1.4%
South East	estimate plus or minus 2%
South West	estimate plus or minus 1.7%
Wales	estimate plus or minus 1.9%
West Midlands	estimate plus or minus 2.1%
Yorkshire and The Humber	estimate plus or minus 2.2%

8 . Strengths and limitations

Strengths

Timeliness

The model-based estimates of quarterly regional gross domestic product (GDP) are available to approximately the same timetable as the release of the UK first estimate of GDP from published data sources of mixed frequencies. This contrasts with our [Regional economic activity, by gross domestic product bulletin](#), which is published annually and, since September 2019, our [GDP, UK regions and countries bulletin](#), which is published quarterly. The delay in publishing these sub-national estimates is because of the data sources being less timely compared with UK estimates of gross value added (GVA).

Peer reviewed

The model has been peer reviewed as part of the Economic Statistics Centre of Excellence (ESCoE) process. Methodologists at the Office for National Statistics (ONS) were involved at various stages of the project and publications.

Performance

The model will continue to be evaluated against our existing predominately Value Added Tax (VAT)-based [GDP, UK regions and countries](#) estimates.

Limitations

The main limitation that applies to modelling (that is not exclusive to this model) is mainly seen during times of economic uncertainty and extreme values. This applies to periods during the coronavirus (COVID-19) pandemic.

Given the model's reliance on estimated historical relationships, shocks in specific regions are unlikely to be detected in the model estimates. Development work is being conducted with a view to adding more timely regional indicators into the model.

Further detail on strengths and limitations can be found in [Model-based estimates of regional GVA: an overview](#).
