36. [Why aren't the thresholds consistent across all personal well-being publications?](#)

1 . What is measuring national well-being about?

[Measuring National Well-being](#) is about looking at “GDP and beyond” to measure what really matters to people. The UK’s Measuring National Well-being programme was launched in 2010 and is based at Office for National Statistics (ONS). The aim is to produce accepted and trusted measures of the well-being of the nation – how the UK as a whole is doing.

A wide range of 43 different headline indicators are monitored regularly in areas such as personal well-being, our relationships, health, what we do, where we live, personal finances, the economy, education and skills, governance, and the natural environment. All of this helps us to measure the progress and well-being of the nation.

ONS published [Measuring National Well-being: Quality of Life in the UK, 2018](#) in April 2018, an article giving the latest snapshot of the nation’s well-being. The report was accompanied by updated [national well-being domains and measures](#) and [an interactive dashboard](#).

Find out more about our approach to Measuring National Well-being on [well-being](#) pages of the ONS website.

2 . What is personal well-being?

Personal well-being is also known as “subjective well-being”. It is about people evaluating their own lives. There are several ways in which this is looked at by researchers who study well-being. These include asking people to evaluate how satisfied they are with their life overall, asking whether they feel they have meaning and purpose in their life, and asking about their emotions during a particular period. Office for National Statistics (ONS) measures of personal well-being ask people to assess each of these aspects of their lives.

Focus groups with members of the public conducted by ONS in 2013 found that the term “personal well-being” is clearer and simpler to understand than “subjective well-being”. In light of this, both the questions and findings from them have been referred to by ONS as “personal well-being” since then.

3 . How are the findings about personal well-being used?

Personal well-being data can contribute to better decision-making, for policymakers, individuals, communities, business and civil society. It complements other measures of progress and quality of life such as unemployment and household income and is used by Office for National Statistics (ONS) to better monitor and understand national well-being.

The uses of personal well-being data are varied, but four main uses have been identified including:

- overall monitoring of national well-being
- use in the policy making process, which includes: identifying needs and targeting policies; policy appraisal; and evaluation and monitoring of policy
- international comparison
- public decision making

Although the Measuring National Well-being (MNW) programme at ONS was only launched in late 2010, the data and measures from the programme are increasingly used across government departments as well as the private sector and third sector organisations.

For further details of a wide range of well-being work across UK government departments, please go to [Wellbeing: Policy and Analysis](#).

ONS is also working with other national statistical offices and international organisations such as the Organisation for Economic Co-operation and Development (OECD) and Eurostat to develop comparable international measures of personal well-being. An example of this is a publication by the OECD providing [guidance to national statistical offices on the measurement of subjective well-being](#). This included many examples from the ONS MNW programme.

4 . What is the difference between personal well-being and subjective well-being?

There is no difference between personal well-being and subjective well-being. Focus groups with members of the public conducted by Office for National Statistics (ONS) in 2013 found that personal well-being is clearer and simpler to understand than subjective well-being. In light of this, both the questions and findings from them have been referred to by ONS as personal well-being since then.

5 . Why measure personal well-being?

Personal well-being is one of many ways in which the Measuring National Well-being programme at Office for National Statistics (ONS) aims to assess the progress of the nation, looking both at standard objective measures such as income and health and at people's own views about their lives. Monitoring personal well-being across the nation year-on-year will help to show how people feel their quality of life changes in relation to changes in circumstances, policies and wider events in society. It will also show how people in the UK evaluate their lives compared with people in other countries across the world.

6 . What measures are included in the personal well-being domain on the Measuring National Well-being dashboard?

The personal well-being domain includes the four Office for National Statistics (ONS) personal well-being questions on life satisfaction, feeling that the things done in life are worthwhile, happiness and anxiety. In addition, the domain also includes a "population mental well-being" measure. This measure uses the Warwick-Edinburgh Mental Well-being Scale (WEMWBS) to assess mental well-being out of a total possible score of 35. The data source for WEMWBS data is [Understanding Society](#). The WEMWBS data are provided alongside the other four personal well-being domain measures as part of the [Measuring National Well-being: Quality of Life in the UK](#) releases.

7 . How does ONS measure personal well-being?

Office for National Statistics (ONS) uses four survey questions to measure personal well-being. People are asked to respond to the questions on a scale from 0 to 10 where 0 is "not at all" and 10 is "completely". The questions are:

- “Overall, how satisfied are you with your life nowadays?”
- “Overall, to what extent do you feel the things you do in your life are worthwhile?”
- “Overall, how happy did you feel yesterday?”
- “Overall, how anxious did you feel yesterday?”

These are known as the ONS4. ONS first added these questions to the Annual Population Survey (APS), in April 2011. The APS is the source of the national estimates of personal well-being in the UK that are published quarterly by ONS.

8 . Are details regarding the validity of testing the four personal well-being questions available?

The four personal well-being questions gained National Statistics status in September 2014. Prior to this, and still ongoing, Office for National Statistics (ONS) has conducted a range of quantitative testing and qualitative testing.

The papers that explain in depth the validity of testing the four questions are as follows. [Overview of ONS phase three cognitive testing of Subjective Well-being Questions \(PDF, 328.2KB\)](#) gives an overview of the qualitative testing of the questions, and [Measuring Subjective Well-being \(PDF, 240.8KB\)](#) covers the background and rationale behind the ONS4 questions.

There are also several other articles documenting the quantitative testing of the ONS4 questions. These are:

- [Initial investigation into Subjective Well-being from the Opinions Survey](#)
- [Summary of results from testing of experimental Subjective Well-being questions – December 2012 \(PDF, 519.1 KB\)](#)
- [Opinions and Lifestyle Survey: Methodological Investigation into Response Scales in Personal Well-being](#)

9 . When are the annual personal well-being results available?

Personal well-being estimates produced from one-year datasets are published on a quarterly basis, whereas, the three-year datasets are published on an annual basis. Personal well-being estimates are published within five months from the end of the reporting period for the quarterly releases. The personal well-being three-year datasets and associated results have been previously published with a time lag of 12 months and 10 months respectively. For more details on related releases, the release calendar provides advance notice of release dates.

10 . Why is there not one composite indicator for personal well-being?

Office for National Statistics uses four questions to measure personal well-being and does not produce one composite measure. The questions were designed to measure distinct aspects of personal well-being (evaluative, eudemonic and affective). It is therefore not appropriate to combine these questions as they are all individually important and together they give a balanced approach to well-being.

For more information on these approaches, and on the background to the personal well-being questions, please see Section 11: How were the four personal well-being questions developed? and Section 12: What is meant by evaluative, eudemonic and affective well-being?.

11 . How were the four personal well-being questions developed?

Office for National Statistics (ONS) personal well-being questions were developed as part of the Measuring National Well-being (MNW) Programme. ONS sought advice from experts working in the field of subjective well-being and consulted with specialists on the National Statistician's MNW Advisory Forum and Technical Advisory Group. Based on this, as well as an extensive programme of question testing, four questions were designed, which provide a concise and balanced approach to the measurement of subjective well-being, drawing on three main theoretical approaches.

For more information about the development and testing of the ONS personal well-being questions, please see the [Measuring Subjective Well-being \(PDF, 240.8KB\)](#) report.

12 . What is meant by 'evaluative' 'eudemonic' and 'affective' well-being?

These are academic terms used to describe different aspects of well-being; the personal well-being questions used by Office for National Statistics (ONS) ask about each of these.

The evaluative approach asks individuals to step back and reflect on their life and make a cognitive assessment of how their life is going overall, or on specific aspects of their life.

The eudemonic approach, sometimes referred to as the psychological or functioning or flourishing approach, draws on self-determination theory and measure such things as people's sense of meaning and purpose in life, connections with family and friends, a sense of control and whether they feel part of something bigger than themselves.

The experience approach focuses on people's positive and negative emotional experiences (or affect) over a short timeframe to measure personal well-being on a day-to-day basis.

More information on the theoretical approaches underpinning the four ONS personal well-being questions is available in [First Annual ONS experimental subjective well-being results](#).

13 . Are the current personal well-being questions likely to change?

Office for National Statistics (ONS) has no plans to change the personal well-being questions. So that the questions are fit for purpose, ONS has done extensive testing using data from the Opinions and Lifestyle Survey, as well as cognitive interviews with members of the public. Academic experts and policymakers have also been consulted as members of our Technical Advisory Group (TAG). The [results from the Opinions and Lifestyle Survey, the cognitive interviews and minutes from the TAG meetings](#) are available.

Together, the findings from this work suggest that the questions do provide robust measures of personal well-being. In future, the value to be obtained from any proposed changes will have to be weighed carefully against the value of maintaining consistent measures that enable comparisons over time.

14 . Are the personal well-being questions part of the government harmonised standards?

The four Office for National Statistics (ONS) personal well-being questions were added to the Harmonisation Programme standards as an “interim standard” for the measurement of personal well-being in January 2014. They were fully approved in June 2017, more information can be found on the [Personal Well-being Harmonisation Principles](#) page on the GSS website.

The Harmonisation Programme is a UK cross-governmental programme of work looking into standardising the way information is collected and the way results are presented and has been led by ONS for several years. The aim of the programme is to make it easier for users to draw clearer and more robust comparisons between data sources.

15 . Is the Annual Population Survey the only survey which includes the ONS personal well-being questions?

No, the Annual Population Survey is one of many surveys in the UK that now include the Office for National Statistics (ONS) personal well-being questions. Other ONS surveys that include the personal well-being questions are: the Wealth and Assets Survey, the Living Costs and Food Survey, the Crime Survey for England and Wales and the Opinions and Lifestyle Survey.

For more information about other surveys across government and more widely that include some or all of the ONS personal well-being questions, please see [Surveys using the four Office for National Statistics personal well-being questions](#). This also provides details of topic coverage and how the data from each survey can be obtained.

16 . Is the Annual Population Survey Personal Well-being dataset the best choice for your analysis?

The following is a summary of some of the main features of the Annual Population Survey (APS) dataset to help researchers decide whether this is the best source of data for their analysis. Further details can be found in the [Personal well-being user guide](#).

Sample size

Over 150,000 adults aged 16 years and over respond to the personal well-being questions, making this the UK’s largest survey containing the Office for National Statistics (ONS) personal well-being questions.

UK coverage

The APS provides a representative sample of adults (aged 16 years and over) living in residential households in the UK.

Levels of geography included

Unitary authorities and counties in England and Wales, local authorities in Scotland, local authority districts in England and district council authorities in Northern Ireland. (Please note that level of geography available on the dataset to the approved researcher depends on the level of user license agreement. Please refer to the [Personal Well-being user guide](#) for further details).

Topic coverage

The APS is primarily a labour market survey so it includes an extensive range of questions that are important for understanding labour market participation, many of which are also useful for the analysis of personal well-being. For example, it includes a wide range of social and demographic questions as well as items about housing, employment and education.

Mixed interview modes

The APS is a mixed mode survey in which people are interviewed either face-to-face or by telephone. The method by which people are interviewed appears to affect responses to the personal well-being questions. This may be particularly relevant to researchers wishing to make comparisons between areas north and south of the Caledonian Canal because all interviews north of the Caledonian Canal are by telephone. More information on interview modes is available under [Section 31](#). Please see the [Personal well-being Quality and Methodology Information \(QMI\) report](#) for further details.

Cross-sectional

Whilst the APS reflects a panel design and attempts are made to interview respondents on more than one occasion, we recommend analysis of personal well-being only on a cross-sectional basis.

Time series

Personal well-being has been collected since the financial year ending 2012.

17 . What is the sample size of the Annual Population Survey personal well-being dataset?

The sample size for the personal well-being responses on the Annual Population Survey is over 150,000 adults aged 16 years and over per year. The sample covers the whole of the UK for the household population but does not include young people aged under 16 years or adults living in communal establishments (for example, nursing homes, homeless hostels or prisons).

18 . Is the Annual Population Survey dataset publicly available?

Yes, there are a range of ways in which the data are made available to the public. A regular set of main estimates from the data are available in Excel spreadsheets published alongside the Personal well-being statistical bulletins. For the most recent personal well-being data, please see our [Well-being homepage](#).

For UK-based academics designated as Approved Researchers, the Annual Population Survey (APS) personal well-being dataset is also deposited with the UK Data Service about six weeks after publication of the Personal well-being statistical bulletins. It is available from the UK Data Service in both End User License and Special License versions. For further information about these options and details of how to access the data, please contact the [UK Data Service](#) directly.

Academics not based in the UK can also access the data either through the [Office for National Statistics \(ONS\) Secure Research Service](#) or through the Secure Data Service of the UK Data Service. In both cases, overseas researchers will need to be approved to use the data and must travel to the UK to use these facilities. Please contact either the [UK Data Service](#) or the [APS team](#) at ONS for further details.

ONS can also provide the data directly to UK civil service statisticians and government researchers. Government analysts interested in this option should please contact the [APS team](#) directly.

A new test version of our personal well-being data is now available through the [ONS Beta website](#). The dataset is interactive and allows users to filter the data as desired.

19 . Are the data robust at lower level geographies?

Office for National Statistics included estimates for the first time at local authority district level in the supporting datasets accompanying the October 2013 statistical bulletin. Sample sizes vary considerably between local authority districts and the data therefore are more robust in some areas than others.

Two different approaches are used to help users assess the quality of data at this level. Where sample sizes are small and could be potentially disclosive, standard disclosure control processes are followed and relevant figures are suppressed. Additionally, estimates with a coefficient of variation (CV) of 20% or greater are also suppressed. The CV indicates the amount of variation in the average (arithmetic mean), that is, the higher the CV, the more the responses are spread out around the average value. Estimates that are provided are colour-coded in the data tables to indicate the quality of the data based on the CV values.

As the Annual Population Survey is a mixed mode survey, researchers should also consider whether interview mode effects may be relevant to their analysis. People who answer the personal well-being questions by telephone appear to give higher ratings on average than those who answer in face-to-face interviews. As those living north of the Caledonian Canal are interviewed exclusively by telephone, care should be taken when comparing areas north of the Caledonian Canal to those South of the Caledonian Canal.

Researchers may wish to disregard any differences between such areas that are only marginally statistically significant.

20 . Is personal well-being data available by industry sector?

Yes, the Annual Population Survey dataset includes information about the respondent's occupation and industry sector using the National Statistics Socio-Economic Classification (SOC 2010-based) (NS-SEC) and Standard Industrial Classification 2007 (SIC 2007) respectively.

21 . What other variables are included in the Annual Population Survey for analysis of personal well-being?

The personal well-being questions can be analysed by various labour market variables using the Annual Population Survey dataset. This includes:

- economic activity
- information about main job and second job where applicable
- self-assessed health
- travel to work
- hours worked
- employment patterns
- union representation
- details of unemployment
- benefit entitlement
- education and training
- health and injury
- personal earnings

Demographic variables available on the dataset include respondent characteristics such as sex, age, relationship status, ethnicity, religion and housing tenure. Geographic variables are also available to allow users to conduct analysis below the UK level. This includes: UK countries, English regions and local authorities. A full list of variables available on the Annual Population Survey personal well-being dataset is available in the [Labour Force Survey user guidance](#).

22 . Are other ONS datasets which include the personal well-being questions available to the public?

Datasets from all the Office for National Statistics (ONS) surveys that include the ONS personal well-being questions are currently available through the UK Data Service to approved researchers. For further information about these datasets and details of how to access the data, please contact the [UK Data Service](#) directly or the relevant survey team at ONS for further details. The contact details are:

- Opinions and Lifestyle Survey: opinions@ons.gov.uk
- Wealth and Assets Survey: wealth.and.assets.survey@ons.gov.uk
- Effects of taxes and benefits on household income personal well-being dataset: hie@ons.gov.uk
- Crime Survey for England and Wales: crimestatistics@ons.gov.uk

23 . What are the sample sizes and coverage of other ONS surveys carrying the personal well-being questions?

The Opinions and Lifestyle Survey (OPN) is cross-sectional and includes a sample of approximately 1,000 respondents per month across Great Britain. Since April 2014, the survey runs every month of the year apart from March, June, September and December. It is a multi-purpose social survey covering different topics of immediate interest each month it is conducted. Government organisations, academic institutions and charities can commission modules on a monthly basis and these have included topics such as public attitudes to road congestion, smoking, drinking, disability and contraception.

Demographic information such as age, sex and marital status is asked of every respondent. As OPN is the main survey used by Office for National Statistics (ONS) for testing variations on the personal well-being questions, the standard ONS personal well-being questions are not asked of the full sample each month. [More information on the OPN](#) is available.

The Wealth and Assets Survey (WAS) is a longitudinal survey covering Great Britain (excluding north of the Caledonian Canal in Scotland and the Isles of Scilly). Approximately 30,000 households were interviewed in wave one, 20,000 in wave two, 21,000 in wave three, 20,000 in wave 4 and 18,000 in wave 5.

WAS collects information about the economic well-being of households by gathering information on level of assets, savings and debt, saving for retirement, distribution of wealth amongst households or individuals and factors affecting financial planning among others. Standard demographic information is also included such as age, sex, marital status and educational attainment. Further details are available in the [Wealth and Assets Survey methodology article](#).

The Effects of taxes and benefits (ETB) on household income personal well-being dataset covers Great Britain and is based on a household survey including approximately 8,000 individuals. As with all other ONS surveys, proxy responses are not accepted for the personal well-being questions so the final sample size for personal well-being data is smaller than the full sample size.

The ETB also includes information on the socio-demographic characteristics of household members (age, sex, marital status) and relationships to one another (for example, spouse, son or daughter, partner). Information is also collected on regular items of expenditure, such as mortgage or rent, insurance, utility bills, education fees and infrequent purchases such as motor vehicles. Details about employment and income, including receipt of benefits, allowances and other financial assets are also included. [Further details about the Effects of taxes and benefits on household income are available](#).

The Crime Survey for England and Wales (CSEW), formerly known as the British Crime Survey (BCS), is a continuous face-to-face victimisation survey in which people aged 16 years and over resident in households in England and Wales are asked about their experiences of a range of crimes in the 12 months prior to the interview. Respondents to the survey are also asked about their attitudes towards different crime-related issues, such as the police and the criminal justice system and perceptions of crime and anti-social behaviour. Until recently the survey did not cover crimes against those aged under 16 years, but since January 2009, children aged 10 to 15 years have been interviewed.

The CSEW has a sample size of 35,000 interviews across the year with adults aged 16 years and over resident in households in England and Wales and an additional 3,000 children aged 10 to 15 years identified through screening at households interviewed for the main sample. Standard demographic information is also included such as age, sex, marital status and educational attainment. Further details are available in the [Crime Survey for England and Wales Quality and Methodology Information \(QMI\) report](#).

24 . Why are some of the data in the reference tables suppressed?

Where data are potentially disclosive due to small sample sizes, the [Government Statistical Service \(GSS\) Statistical Disclosure Control and Communicating Uncertainty and Change](#) processes are applied and the relevant figures are suppressed.

Any estimate that has a coefficient of variation (CV) of 20% or greater is also excluded from the published datasets as part of data quality assurance processes. The CV indicates the amount of variation in the average (arithmetic mean): the higher the CV, the more the responses are spread out around the average value. Estimates that are provided in the Excel datasets are colour-coded to indicate the quality of the data based on the CV values.

For more information, please see the [Personal well-being Quality and Methodology Information \(QMI\) report](#).

25 . How long is it expected to take to ask the four personal well-being questions on a survey?

On the Annual Population Survey, it takes on average about a minute and a half for the interviewer to ask the four questions and for respondents to give their answers. This includes the interviewer reading out the introduction to the personal well-being questions.

26 . Does the inclusion of the personal well-being questions on existing surveys affect overall response rates?

There is no evidence that the personal well-being questions have had any adverse effects on response rates on the surveys in which they have been included at Office for National Statistics (ONS). Additionally, all the personal well-being questions have very low rates of item non-response (typically around 1% non-response for each of the four questions).

We welcome further feedback on response rates from others who have used the questions on their surveys. Please contact us via email at QualityOfLife@ons.gov.uk.

27 . What is the recommended placement of personal well-being questions in a survey?

Ideally, the four personal well-being questions should be placed at the beginning of the survey, immediately after the main demographic questions. This is where the questions appear on the Annual Population Survey. This was selected as the best place for the questions following extensive qualitative testing and consultations with academic experts.

Important considerations are allowing sufficient time for the development of rapport between the interviewer and the respondent before asking potentially sensitive questions about well-being, and asking the questions early enough in the interview to avoid any bias from preceding questions on other topics such as health or employment.

For more details please see the Personal well-being [Quality and Methodology Information \(QMI\) report](#).

28 . Are all responses kept even if the respondent does not answer all four questions?

Yes, all responses to the personal well-being questions are kept even if the respondent has not answered all four questions.

29 . If the respondent gives exactly the same rating to all four personal well-being questions, are the answers eliminated?

All responses are retained even if a respondent gives the same response to all four questions.

30 . Are show cards used during the interview?

The Annual Population Survey (APS) uses both telephone and face-to-face data collection methods. This use of mixed data collection methods makes it unfeasible to use show cards consistently among all respondents to the APS.

31 . Does interview mode affect responses to the personal well-being questions e.g. telephone interviews compared with face-to-face?

Different data collection methods do appear to affect how people respond to the personal well-being questions. Findings from the Annual Population Survey show that, on average, people rate each aspect of their well-being more positively when interviewed by telephone than when interviewed face-to-face by an interviewer.

The relationship between the mode of interview and average responses to the personal well-being questions has also been examined using regression analysis to hold other possible influences on personal well-being constant. This shows the same pattern found in descriptive statistics; on average, people give more positive responses when interviewed by telephone than when interviewed face-to-face.

The findings are statistically significant for each question, suggesting that they are not due to chance alone. It is challenging to account for mode effects when using statistics. Mode effects can be controlled for in regression models by including mode of interview as an independent variable, and we advise researchers to do this in any regression analysis involving the personal well-being data.

When considering the high-level national estimates published by Office for National Statistics (ONS), the impact of mode is statistically significant but in general small and roughly consistent over the period for which data are available, meaning that mode effects may be unimportant to any substantive conclusions being drawn.

Mode effects may have a greater impact on comparisons between lower-level estimates (such as local area statistics) for two different reasons: different groups may have different balances of telephone and face-to-face response, and the impact of mode may differ by group. As all interviews in Scotland north of the Caledonian Canal are conducted by telephone, we would advise researchers to disregard any marginally statistically significant findings based on comparisons between areas north and south of the Caledonian Canal.

32 . Can the personal well-being questions be answered by proxy?

No. The aim is to ask people to assess their own well-being, so all answers must be given directly by the respondent. Proxy responses (on behalf of someone else in the household) are never accepted.

33 . Why do ONS use the 0 to 10 scale?

Office for National Statistics (ONS) decided on an 11-point scale from 0 to 10, where 0 is "not at all" and 10 is "completely", for all the questions following a review of the literature on the measurement of personal well-being and in light of expert academic advice. This ensures the scales between the questions are consistent, which helps respondents to answer them more easily. Also, 11-point scales are commonly used across other surveys of interest and using the same type of scale aids comparisons.

For more information about the use of the 0 to 10 scale, please see [Opinions and Lifestyle Survey: Methodological Investigation into Response Scales in Personal Well-being \(PDF, 485.6KB\)](#)

34 . Why are findings presented using both ‘averages’ and responses in banded groups?

These different ways of looking at the data are useful for different purposes.

Although average ratings are easy to understand and provide a helpful summary measure to compare responses year-on-year and across areas, the average does not show the proportion of people who gave each response on the 0 to 10 scale. The average cannot shed light on whether responses are evenly distributed along the 0 to 10 scale, or the proportions of people rating their well-being at the highest and lowest levels. For this reason, relying only on average ratings might mask important differences in how people rate their well-being.

This is why the data are also presented in terms of the proportions of people who rated each aspect of their well-being within a particular range on the 0 to 10 scale. For the life satisfaction, worthwhile and happiness questions, ratings are grouped in the following way:

- 0 to 4 (low)
- 5 to 6 (medium)
- 7 to 8 (high)
- 9 to 10 (very high)

For the anxiety question, ratings are grouped differently to reflect the fact that higher anxiety is associated with lower personal well-being. The ratings for anxiety are grouped as follows:

- 0 to 1 (very low)
- 2 to 3 (low)
- 4 to 5 (medium)
- 6 to 10 (high)

35 . Why are the ratings on the 0 to10 scale grouped as they are?

The ratings on the 0 to 10 scale are grouped this way because this results in fairly even groups of people who rate their well-being in different ways. For example, the mean rating for the positive questions is around 7 to 8 and there are similar percentages of people rating their positive personal well-being as 5 or 6, 7 or 8 and 9 or 10. This is helpful for analysis purposes.

Additionally, qualitative testing has shown the mid-point of the scale (5) acts as an important cut-off for respondents for assessing their own well-being, with responses below five seen largely as a negative response.

The thresholds used for personal well-being have been tested. It was concluded that the thresholds should be kept as they currently are until further work takes place, as there seem to be differences in the characteristics and circumstances of those reporting 0 to 4 for their personal well-being and those reporting 5 or 6.

Our initial analysis suggests that people rating life satisfaction, worthwhile and happiness as 4 or below on the scale are much more likely to have the characteristics and circumstances associated with poor well-being than those rating these aspects of well-being even one point higher (5 or above), who are rating their own well-being more positively.

While the definition of lowest well-being should not be overly narrow, it needs to be narrow enough to offer clear insights into the lives of those with the poorest well-being. This will enable clearer decision-making about what can be done to support them.

Ratings are grouped in a similar way for the anxiety question, but as most people tend to rate their anxiety lower than 5 (indicating higher well-being), the ratings are grouped in a way which reflect this difference.

As policy-makers are particularly interested in people reporting the highest or lowest levels of personal well-being, looking at the ratings in this way helps to shed more light on these groups.

We will continue to monitor whether our current thresholds are providing the most useful information.

36 . Why aren't the thresholds consistent across all personal well-being publications?

As the personal well-being data have only been collected since April 2011, Office for National Statistics (ONS) has tried various methods of analysing and presenting the findings to see which best meets the needs of those who use the data.

For example, in the [First ONS Annual Experimental Personal Well-being Results](#), the data were published for the first time on smaller geographic areas such as unitary authorities and counties. To ensure that the estimates were based on larger sample sizes, the ratings on the 0 to 10 scale were divided into two groups rather than four. For the questions about life satisfaction, feeling that the things done in life are worthwhile, and happiness yesterday, the ratings were grouped together in the following way:

- 0 to 6 (low to medium)
- 7 to 10 (high to very high)

For the anxiety yesterday question, the ratings were grouped as follows:

- 0 to 3 (very low to low)
- 4 to 10 (medium to high)

A different approach was taken in the October 2013 statistical bulletin, [Personal Well-being Across the UK](#). In this case, the data were published for more local areas for the first time such as unitary authority and local authority level. Instead of combining groups to create larger sample sizes, the decision was taken to suppress the data where it did not meet pre-defined quality standards (based on the size of the coefficient of variation).
